

Figure 1. ECG showing ST elevation on admission (A), and basal early repolarization after treatment (B). Chest radiograph showing linear radiolucency in the left paracardiac region (C), (arrows).

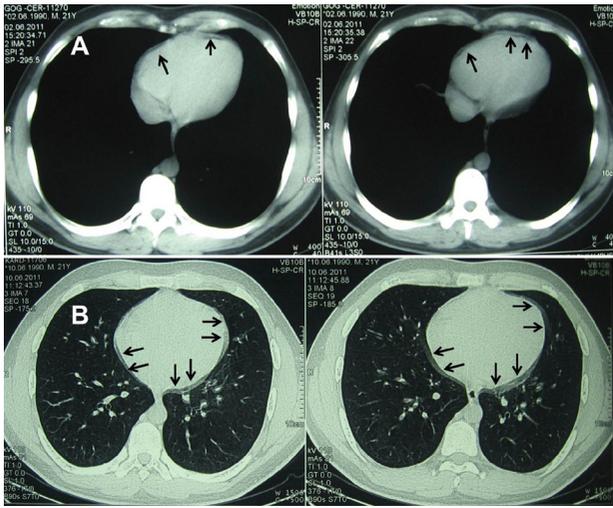

Figure 2. Computed tomography scan of the chest reveals pericardial thickening with minimal radiolucency mimicking pneumopericardium (A), (arrows). High resolution computed tomography depicts that the pericardial thickening caused radiolucency (B).

A 21-year-old male patient with no significant past medical history presented to the emergency department three days after the acute onset of precordial chest pain worsening in the recumbent position and exacerbated by deep inspiration. He also had cough lasting 1 week. The patient denied having any fevers, chills, hemoptysis, nausea, or vomiting. He did not have any recent trauma or surgeries. He had a pack-day history of smoking cigarettes. On physical examination, the blood pressure was 110/70 mmHg, the pulse was 39 beats/min, respirations were 14/min, temperature was 36.7°C and oxygen saturation was 95% while breathing room air. Electrocardiogram showed sinus bradycardia with early repolarization and ST/T ratio was 0.26 in V5 (Figure 1). The chest radiograph showed linear radiolucency in the left paracardiac region without evidence of pneumothorax (Figure 1). Although computed tomography (CT) scan of the chest revealed pericardial thickening with minimal radiolucency mimicking pneumopericardium, there was no evidence of pneumothorax, bullous changes, or bronchopleural fistula (Figure 2). High resolution computed tomography (HRCT) subsequently depicted that the pericardial thickening caused

radiolucency of the chest radiograph which was appeared like pneumopericardium (Figure 2). The patient's symptoms improved with indomethacin and colchicine therapy. Pericarditis and pneumopericardium are important causes of chest pain. Pneumopericardium is defined as the presence of free air or gas in the pericardial sac. It is a rare, usually self-limited disease primarily affecting young men. Differentiating the ECG of acute pericarditis from the normal variant with early repolarization is difficult, and serial ECGs in conjunction with the clinical setting are required. Additionally, an ST/T ratio > 0.25 in V5 or V6 may discriminate the ECGs of patients with acute pericarditis from normal variants with early repolarization.

Consequently, pneumopericardium is a rare condition, less common than either isolated pneumothorax or pneumomediastinum. Nevertheless, clinicians should be familiar with this differential diagnosis of chest pain and its clinical and radiographic manifestations, since prompt recognition and treatment of potential complications may be life saving.
